## Computational Complexity in Column Sums of Symmetric Group Character Tables and Counting of Surfaces

jeudi 21 novembre 2024 14:50 (50 minutes)

The character table of the symmetric group  $S_n$ , of permutations of n objects, is of fundamental interest in theoretical physics, combinatorics as well as computational complexity theory. We investigate the implications of an identity, which has a geometrical interpretation in combinatorial topological field theories, relating the column sum of normalised central characters of  $S_n$ , to a sum of structure constants of multiplication in the centre of the group algebra of  $S_n$ . The identity leads to the proof that a combinatorial computation of the column sum belongs to complexity class #P. The sum of structure constants has an interpretation in terms of the counting of branched covers of the sphere. This allows the identification of a tractable subset of the structure constants related to genus zero covers. We use this subset to prove that the column sum for a conjugacy class labelled by partition  $\lambda$  is non-vanishing if and only if the permutations in the column sum is in complexity class P.
