Definition

$$H: \{0,1\}^* \to \{0,1\}^n$$

It's easy to compute H(M||L) given H(M)

SHA-1, SHA-2, MD5

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

- $H: \{0,1\}^* \to \{0,1\}^n$
- Given, M and H(M) find L s.t. H(L) = H(M)
- For a random *L*:

$$Pr\left[H\left(M\right)=H\left(L\right)\right]=\frac{1}{2^{n}}$$

▲□▶▲□▶▲□▶▲□▶ ▲□ ● ● ●

- $H: \{0,1\}^* \to \{0,1\}^n$

▲□▶▲□▶▲□▶▲□▶ ▲□ ● ● ●

• On average 2^{*n*} different *L* to get a second-preimage.

If *M* has *k* blocks, then $Pr[H(\cdot) = h_i] = \frac{k}{2^n}$, thus we need around $\frac{2^n}{k}$ trials.

However,

- We need around 3377 TB to store 2⁴⁸ hashes.
- The largest memory we could get is 98.3 TB across 512 servers!

・ コ ト ・ 西 ト ・ 日 ト ・ 日 ト

• Each server has 192GB Memory

▲ロ ▶ ▲周 ▶ ▲ ヨ ▶ ▲ ヨ ▶ ● の Q @

Only store *h_i* that ends with *d*-zeros

- Memory usage is $2^{-d} \times before$
- Increases the CPU work by the factor 2^d

・ロト ・ 理 ・ ・ ヨ ・ ・ ヨ ・ うらぐ

Only store h_i that ends with d-zeros

- Memory usage is $2^{-d} \times before$
- Increases the CPU work by the factor 2^d

Or even better, with above increase the long message size by 2^x

- Memory usage is $2^{x-d} \times before$.
- Increases CPU work by the factor 2^{*d*-x}
- Sweet spot $x := \frac{d}{2}$

 a 2nd-preimage is found after a CPU generates 2^{n/2} random digests and memory accesses.

• # operations =
$$\underbrace{2^{n/2}}_{CPU} + \underbrace{2^{n/2}}_{memory}$$

 a 2nd-preimage is found after a CPU generates 2^{n/2} random digests.

#operations = Х = 2ⁿ # CPUs #operations/CPU

• Instead of 4,660 cpu hours, we need 290,816 cpu hours.

- The attack cost jumped from 140€to 8724€.
- Using only disitinguished point the attack would cost:
 - 1,638,400 cpu hours
 - i.e. 49k €

Thank you!
